

Enhanced subgroup identification in heterogeneous clinical courses of disease burden using a machine learning score from CT images

Grace Hyun J. Kim

Professor,

David Geffen School of Medicine, Radiological Science,

Fielding School of Public Health, Biostatistics

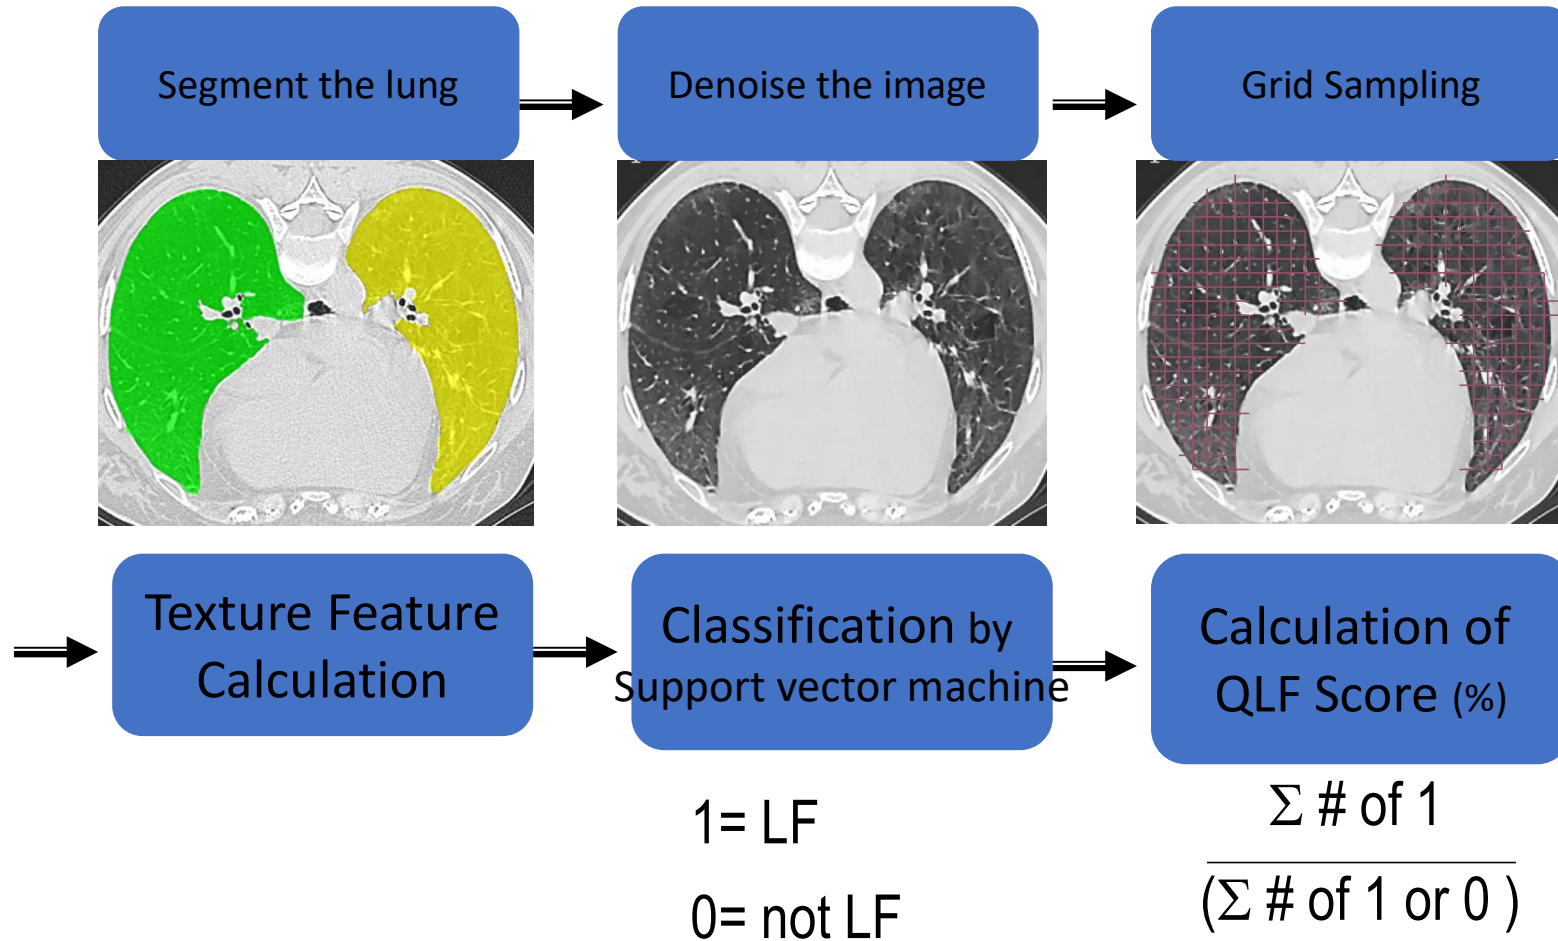

UCLA

HTA session on Monday, June 17, from 15:15 to 16:30

Background

- Quantitative lung fibrosis (QLF) score has been developed using non-contrast computed tomography (CT) by applying machine-learning (ML) algorithm with AUC=0.96
- The performance QLF score has been evaluated in clinical trials as a secondary or an exploratory endpoint
- However, the study visits of a clinical trial have the pre-specified visits to evaluate a study drug. Scans from clinical care/ real-world CT are used to test patient's response after initiating a new therapy or confirmation of worsening.

1. One Pipeline: Automated Fibrosis Classifier & Quantitative Lung Fibrosis (QLF)
Score: *starts from 30 slices, now 300 slices, large cohorts, need to be faster*

Denoised vs. Original Images

Radiomics (texture)

Texture features calculation within a window (e.g. 12x12x12 for isotropic)

Example) Co-occurrence Matrix: within a window, set a categorical level (bin size) of HU intensities and generate co-occurrence matrix (P). Here, HU intensities were set to 4 levels and P was generated for predetermined 0° with distance 1.

3	0	1	1
0	0	1	1
0	2	2	2
2	2	3	3

$$P_{0^\circ,1} = \begin{pmatrix} p(0,0) & p(0,1) & p(0,2) & p(0,3) \\ p(1,0) & p(1,1) & p(1,2) & p(1,3) \\ p(2,0) & p(2,1) & p(2,2) & p(2,3) \\ p(3,0) & p(3,1) & p(3,2) & p(3,3) \end{pmatrix} = \frac{1}{12} \begin{pmatrix} 1 & 2 & 1 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 3 & 1 \\ 1 & 0 & 0 & 1 \end{pmatrix}$$

Angular Second Moment : $f_1 = \sum_i \sum_j \{p(i,j)\}^2$

Entropy : $f_2 = -\sum_i \sum_j p(i,j) \log\{p(i,j)\}$.

Contrast : $\sum_i \sum_j (i-j)^2 p(i,j)$

HRCT scans: QLF score

Section 3. Interstitial Lung Disease (ILD) Assessment

ILD Involvement Percentages:

Regions	Ground Glass (%)	Honeycombing (%)	Fibrosis (%)
Whole Lung	17.4	0.1	7.4
Left Lung	20.0	0.1	11.0
Right Lung	15.3	0.1	5.2
Left Upper Lobe	19.4	0.1	8.9
Left Lower Lobe	23.6	0.1	13.5
Right Upper Lobe	16.0	0.1	3.6
Right Middle Lobe	15.7	0.0	2.8
Right Lower Lobe	14.5	0.2	7.4

Approve

Modeling and its notation

1. $f(t) = e^{-dt} + e^{gt} - 1$

d represents a decrease pattern over time, g , represents an increase in QLF score, where initial decrease is followed by progressive increase.

2. $f(t) = (\phi)e^{-dt} + (1 - \phi)e^{gt}$

** When $\phi = 0$, this model is labeled as gx , and it describes consistent progressively increase pattern over time, with d being eliminated.

- ** When $\phi = 1$, this model is labeled as, with g being eliminated.

Examples) idiopathic inflammatory myopathy-associated interstitial lung disease: follow-up times are varied

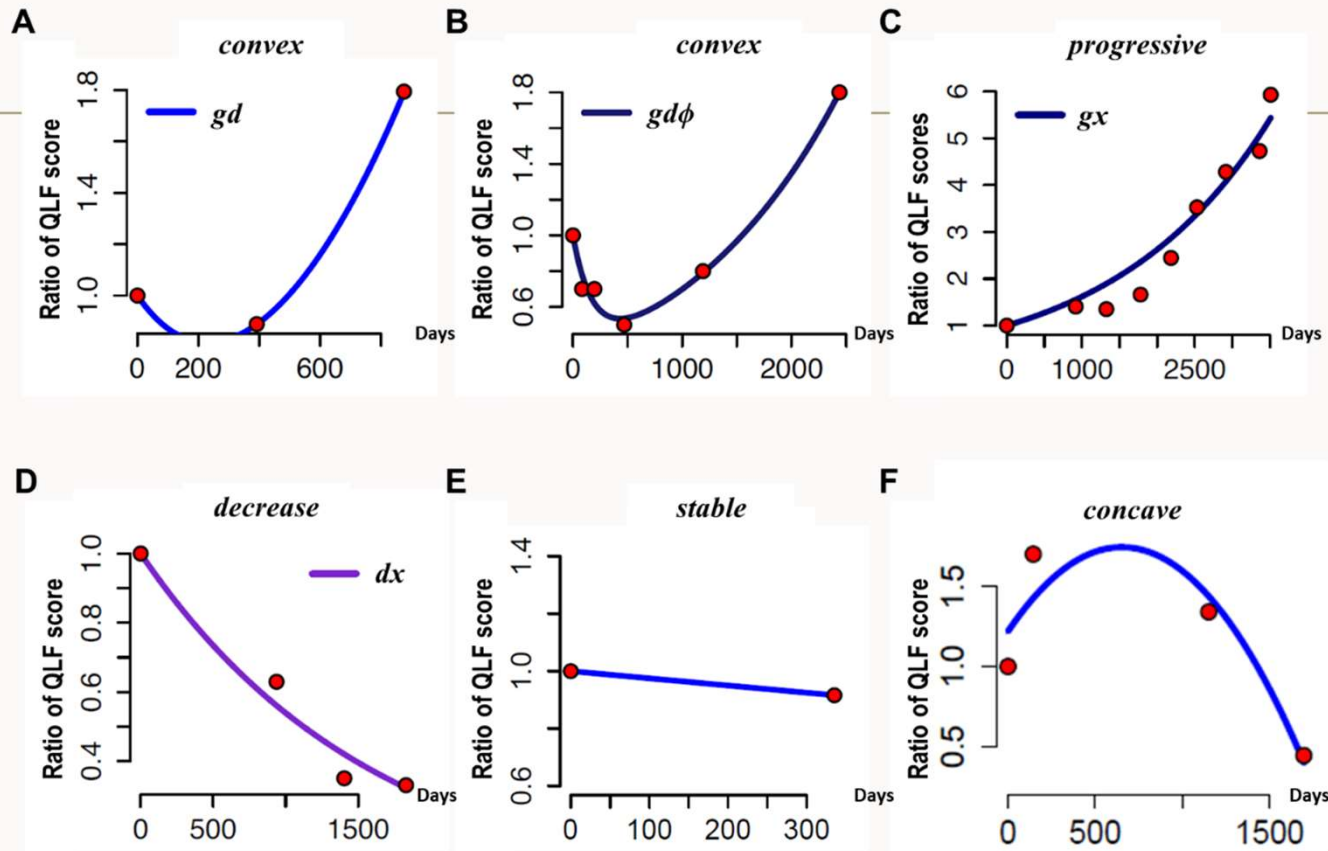

Table 1. Categorization of total subjects according to growth-rate model application

Assigned patterns	Evaluable – Fitted			Evaluable – Not fitted by the AIC	Not evaluable by the model
	decrease (dx)	progressive (gx)	convex ($gd + gd\phi$)	concave	stable
n (%)	20 (25.0)	19 (23.8)	10 (12.5)	22 (27.5)	9 (11.2)

Conclusion/Summary

- Growth-rate model can be practical approach, revealing five distinct patterns over time that substantiate the dynamic changes.
- By the pattern groups, characterizing and estimating a progression rate (g) is feasible
- Easy interpretation of complex data for the disease course, potentially contributing to more personalized treatment strategies and improved patient care.

Discussion

- Future research with larger datasets and adopting prospective registry may provide firm evidence for the efficacy of our approach and expand upon our findings.

Thank you

- **UCLA CVIB group, CTD-ILD for supporting this study. Special thank you Jiahao Tian, You-Jung Ha**
